## Squaring the circle and number $\pi$

Steva Stojilković<br>Zemun, Serbia<br>email: steva.sto@sbb.rs

#### Abstract

This paper presents an attempt to finally solve the problem of constructing the squares of the same surface of the given circle, in a simple way: by determining the exact value of the number $\boldsymbol{\pi}$. The value of this constant thus far implies the following: in the Universe there is no square of the same surface as the given circle!?

It's pointless. The number $\boldsymbol{\pi}$ is not irrational, so it is not transcendental number either.
Key words: Geometry; Number Pi; Squaring the circle; Sphere geometry.

## 1 Introduction

Elementary logic in the case of the Squaring the circle would read like this: The square of approximately the same surface as the given circle can be increased or decreased for immeasurably small values. At one point, that square must achieve an identical surface. Since logical thinking is a prerequisite for effective dealing with any kind of work, instead of calculating the decimal number of the number $\boldsymbol{\pi}$, we will find its exact value.

## 2 Pi is a rational number

Pi or $\boldsymbol{\pi}$ is a mathematical constant and is defined as the ratio of the circumference and circle diameter. Pi is a rational number because it can be expressed as a quotient of two integers:

$$
\frac{405}{128} \quad \pi=3.1640625
$$

## 3 Accuracy, Exactness, Axiom

If the proposed value of the number $\boldsymbol{\pi}$ would not become an axiom (an indisputable, irrefutable fact), this would mean that it was not true at all.
Since axioms are mutually independent and one can not prove by another, the only reliable way of checking accuracy is the exact mathematical calculation.

## 4 Squaring the circle

Since Pi is a rational number, this means that it is constructible.
Example:
$r=3.14227$
$a=r \sqrt{ } \pi=5.58941075055973$

$$
\begin{aligned}
& A=\boldsymbol{\pi} r^{2}=\mathbf{3 1 . 2 4 1 5 1 2 5 3 8 4 7 2 7} \\
& \boldsymbol{A}=\boldsymbol{a}^{2}=\mathbf{3 1 . 2 4 1 5 1 2 5 3 8 4 7 2 7} \\
& C=2 r \pi=19.88467734375
\end{aligned}
$$

5 If $r=2$ then $\pi r^{2}=a^{2}=2 r \pi$
$r=2$
$a=r \sqrt{ } \pi=3.55756236768943$

$$
\begin{aligned}
& A=\pi r^{2}=\mathbf{1 2 . 6 5 6 2 5} \\
& A=a^{2}=\mathbf{1 2 . 6 5 6 2 5} \\
& C=2 r \pi=\mathbf{1 2 . 6 5 6 2 5}
\end{aligned}
$$

$$
\frac{A}{C}=\frac{r}{2}=1 \quad \text { from here follows } \quad \frac{\pi r^{2}}{2 r \pi}=\frac{r}{2}
$$

## 6 Surface Area and Volume of a Sphere

If $r=3$ then $A=V$

$$
\begin{aligned}
& \mathbf{A}=4 \mathrm{r}^{\mathbf{2}} \pi=\mathbf{1 1 3 . 9 0 6 2 5} \\
& \mathbf{V}=\frac{4}{3} \mathrm{r}^{3} \pi=\mathbf{1 1 3 . 9 0 6 2 5}
\end{aligned}
$$

We calculate the surface $\boldsymbol{A}$ by simply multiplying the Circumference and the diameter :

$$
\begin{gathered}
\mathrm{C}=2 \mathrm{r} \pi=6 \pi=18.984375 \\
A=C d=18.984375 * 6=\mathbf{1 1 3 . 9 0 6 2 5}
\end{gathered}
$$

$71 \mathrm{rad}=56 \frac{8}{9}$

$$
\mathbf{1}^{\circ}=\frac{2 \pi}{360} * 56 \frac{8}{9}=0.017578125 * 56 \frac{8}{9}
$$

## 8 Unsuccessful attempts throughout history

All theoretical calculations of Pi did not lead to the correct result: (from Wikipedia)

- geometric Archimedes (223/71< $<22 / 7$ ), Ptolemseus $(3,1416)$, Tsu Ch'ung-chih(355/113), AlKhwa rizmi... Van Ceulen ( 35 decimals)...
- arithmetic (Fransoa Viet, 1593), (John Wallis, 1616-1703), (James Gregory, 1638-75), (John Machin, 1680-1751), (William Shanks, 1812-82)...

The most approximate value that has been used throughout history is: "Indian sources by about 150 $B C$ treat as $\underline{\sqrt{10}} \approx 3.1622$. " "In ancient China, values for $\pi$ included $\underline{\sqrt{10}}(100 \mathrm{AD}$, approximately 3.1623)." wikipedia

The construction of Inscribed polygons in a circle was a logical way to determine the exact value of Pi. We suppose it will be interesting for mathematicians to determine why this good method has not led to complete success.

## 9 Conclusion

Now it's only left for mathematicians to check here the exposed value of number Pi. The quest for this natural constant has a long history: from Egyptian and Chinese mathematicians, through the famous Archimedes, whose approximation is $22 / 7$ most well-known. This is understandable, given its frequent use in natural science. Everything in the Universe is a spherical shape, and on the planet Earth problem the Squaring the circle became a philosophical and sociological phenomenon. Perhaps the representatives of these teachings could answer the question, what happened with logical thinking: that computers were tuned to look for the exact value of the number Pi, instead of counting trillion decimals, would they be able to calculate?!?

Of course you would.

## Appendix

## Alternative methods of calculating the circle geometry

(a) In ancient Egypt, they used an interesting way of calculating the surface of the circle, which was very precise: $\quad d-\frac{d}{9}$. The result of this formula is multiplied by the same number.
Example: d=27

$$
\begin{aligned}
& 27-\frac{27}{9}=24 \\
& \mathrm{~A}=24 * 24=576
\end{aligned}
$$

We will now compare the accuracy of the calculation:

$$
\begin{array}{rl}
d=27 \Rightarrow r=13.5 & A=\pi r^{2} \\
& \mathrm{~A}=3.1640625 * 13.5^{2}=\mathbf{5 7 6 . 6 5 0 3 9 0 6 2 5}
\end{array}
$$

(b) By using the same Egyptian method (number 9), we can calculate the surface of a circle by means of circumference. Of course, this is possible now, when we know the exact value of Pi:
$C=2 r \pi$

$$
\begin{gathered}
C=27 * 3.1640625=85.4296875 \\
A=\left(C-\frac{C}{9}\right)^{2} / 10 \\
\mathrm{~A}=\mathbf{5 7 6 . 6 5 0 3 9 0 6 2 5}
\end{gathered}
$$

(c) The volume of a sphere that is twice as large can be calculated as follows: $\left(V-\frac{V}{9}\right) * 9$

For radius $r=20$, the volume is $\mathrm{V}=33750$
For radius $r=40$, the volume is

$$
\left(3370-\frac{3370}{9}\right) * 9=270000
$$

Since $\left(\chi-\frac{\chi}{9}\right) * 9=8 \chi$, we can directly multiply by 8: $\quad \mathrm{V}=3370 * 8=\mathbf{2 7 0 0 0 0}$

$$
\text { we will check in the school way: } \frac{4}{3} 40^{3} * 3.1640625=270000
$$

(d) Finally, by comparing:
section $5 \quad \boldsymbol{\pi} \mathbf{r}^{2}=\mathbf{2 r} \boldsymbol{\pi}=\mathbf{1 2 . 6 5 6 2 5}(r=2)$
section $6 \quad \mathrm{~A}=\mathrm{V}=113.90625(r=3)$

$$
\text { the quotient is } \frac{113.90625}{12.65625}=\frac{\mathbf{3 6 \pi}}{\mathbf{4 \pi}}=\mathbf{9}
$$

The table clearly shows why the circle is the most perfect shape.

Circle $\quad \pi=3.1640625 \quad$ Sphere

| r | $\pi r^{2}$ | $2 r \pi$ | r | A $4 r^{2} \pi$ | $V 4 / 3 r^{3} \pi$ | V/A |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | $\underline{12.65625}$ | 12.65625 | 1 | 12.65625 | 4.21875 | 0.33333 | 113 |
| 4 | 50.625 | 25.3125 | 2 | 50.625 | 33.75 | 0.66666 | 213 |
